#### E. Dean Young and Jiazhen Xia

Plans to prove three variations of the Whitehead theorem and the exactness of three variations of the Puppe sequence of homotopy groups for based ∞-groupoids in Lean 4, with extensive use of Mathlib's categories, functors, natural transformations, Eilenberg-Moore theory, pullbacks, products, simplices, cube, boundary of simplex, boundary of cube, horns, inner horns,

Copyright © October 19th 2023 Elliot Dean Young. All rights reserved.

We wish to acknowledge the collaborative efforts of E. Dean Young and Jiazhen Xia ( $\boxed{????}$ ). The first author initially formulated the extensive outline and twelve goals presented in this research, and both made valuable contributions refining, extending, and implementing them.

- 1. Categories (see Mathlib's Category X here; these can be bundled into category)
- 2. Functors (see Mathlib's Functor C D here; these can be bundled into functor)
- 3. NaturalTransformation (see Mathlib's NaturalTransform F G here; these can be bundled into natural\_transform)
- 4. Equations (see Mathlib's NatExt here; these are related to our equation)
- 1. IntCat : Cat  $\rightarrow$  Cat
- 2. IntPrShf:  $(X : Cat) \rightarrow (C : (IntCat X)) \rightarrow Cat$
- 3. IntGrpd : Cat  $\rightarrow$  Cat
- 4. IntAct :  $(X : Cat) \rightarrow (G : (IntGrpd X)) \rightarrow Cat$
- 5. IntGrp : Cat  $\rightarrow$  Cat
- 6.  $IntAct_0 : (X : Cat) \rightarrow (G_0 : (IntGrp X)) \rightarrow Cat$

Below is a complete list of the symbols we define and the theorems we define and prove:

#### 2. Introduction

The main goal of this text is to prove the Whitehead theorem concerning based connected attaching-map-complexes for the case of a homotopy category of SSet with a lifting condition. The book "Galois theories" by Borceux and Janelidze deserves special mention as an inspiration for the present project. That book details how to think about Galois theory using internal groupoids, internal G-presheaves, monadicity, comonadicity, and the constructions involved in Eilenberg-Moore theory.

Here are the three Whitehead Theorems which form our main three goals:

- (a) (The Whitehead theorem for  $\infty$ -categories)  $\forall (E:\vec{D}(\infty\text{-Cat})), \forall (B:\vec{D}(\infty\text{-Cat})), \forall (F:E \longrightarrow B), \forall (G:E \longrightarrow B), (\forall (n:Nat), (\vec{\pi}_n F = \vec{\pi}_n G)) \rightarrow F = G$ , where  $\vec{\pi}_n$  is notation for  $\vec{\pi}$  n.
- (b) (The Whitehead theorem for  $\infty$ -groupoids)  $\forall (E:\vec{D}(\infty\text{-Grpd})), \forall (B:\vec{D}(\infty\text{-Grpd})), \forall (F:E \longrightarrow B), \forall (G:E \longrightarrow B), (\forall (n:Nat), (\vec{\pi}_n F = \vec{\pi}_n G)) \rightarrow F = G$ , where  $\vec{\pi}_n$  is notation for  $\vec{\pi}$  n.
- (c) (The Whitehead theorem for based connected  $\infty$ -groupoids)  $\forall$ (E:D( $\infty$ -Grpd<sub>0</sub>)), $\forall$ (B:D( $\infty$ -Grpd<sub>0</sub>)), $\forall$ (F:E  $\longrightarrow$  B), $\forall$ (G:E  $\longrightarrow$  B),( $\forall$ (n:Nat),( $\pi_n$  F =  $\pi_n$  G))  $\rightarrow$  F = G, where  $\pi_n$  is notation for  $\pi$  n.

We will use the following models in the theorem above:

- (i)  $\infty$ -Cat is the category of quasicategories.
- (ii)  $\infty$ -Grpd is the category of simplicial sets with the Kan lifting condition.
- (iii)  $\infty$ -Grpd<sub>0</sub> is the category of based connected simplicial sets with the Kan lifting condition.

The operations require great care in their definition. The existence of a base point makes  $\pi_n$  relatively easy to define, while  $\vec{\pi}_n$  and  $\vec{\pi}_n$  require careful consideration and get much larger by comparison:

(i) 
$$\vec{\pi}_n : \infty$$
-Cat  $\longrightarrow$  Set

(ii) 
$$\vec{\pi}_n : \infty$$
-Grpd  $\longrightarrow$  Set

(iii) 
$$\pi_n : \infty\text{-}\mathsf{Grpd}_0 \longrightarrow \mathsf{Set}$$

we also form

- (i)  $\vec{D}(\vec{\pi}_n) : \vec{D}(\infty\text{-Cat}) \longrightarrow \vec{D}(\text{Set}) \simeq \text{Set}$
- (ii)  $\vec{\mathbf{D}}(\vec{\pi}_n) : \vec{\mathbf{D}}(\infty\text{-Grpd}) \longrightarrow \vec{\mathbf{D}}(\operatorname{Set}) \simeq \operatorname{Set}$
- (iii)  $D(\pi_n)$ :  $D(\infty\text{-Grpd}_0) \longrightarrow D(\text{Set}) \simeq \text{Set}$ and
  - 1.  $\vec{\Omega}$ :  $\infty$ -Cat is the internal hom functor  $[\Delta^1, -]$  (directed path space)
  - 2.  $\vec{\Omega}$  :  $\infty$ -Grpd  $\longrightarrow \infty$ -Grpd is the internal hom functor [I,-] (path space)
  - 3.  $\Omega$  is the loop space functor

The first of the Whitehead theorems, (a), is the most abstract. The third, (c), is the one from Whitehead's original papers. The second forms a nice intermediate between the two.

The choice of quasicategories gives nice integration with Mathlib's existing features (though technically only the inner horns and simplices are defined, not even the category of quasicategories itself), a possible benefit over a more "synthetic" approach based on forcing the three Whitehead theorems and three Puppe sequences at the outset (along with the functors, natural isomorphisms, and equations in the first several pages).

The main technical feature in the proofs of these theorems concerns a lifting property which successively lifts a homotopy\*\*\* along a single attachment of  $\Delta^n$  along its boundary  $\partial \Delta^n$ . A homotopy  $h: \partial \Delta^n \times \Delta^1 \longrightarrow Y$  between  $f, g: \partial \Delta^n \longrightarrow Y$  extends to a map  $H: \Delta^n \times \Delta^1 \longrightarrow Y$ . H(-,1) and g match on  $\partial \Delta^n$ , producing a map  $f: X \longrightarrow Y$ , where X consists of two copies of  $\Delta^n$  glued together at the boundary. Consider a space X' formed as a quotient of  $\Delta^n \times \Delta^1$  by  $\partial \Delta^n \times \Delta^1$ . There is a map  $\phi: X \longrightarrow X$ '. An induction hypothesis on f and g involving  $\pi_n$  ensures that the aparent map f if f if f is along f, producing a map from f is constant on f in f is constant on f in f is constant on f in f is along different endpoints. Altogether this produces a homotopy between f and g.

\*\*\* Note that a homotopy here is to do with the directed derived category of an overcategory  $D(\infty\text{-Cat/C})$ , and it consists of really a sequence of compatible directed homotopies with the odd morphisms formed from reversed copies of  $\Delta^1$ . Really we have two such categories, one of which consists of formal words, and another which involves  $\infty$ -categories and  $\infty$ -functors in the image of rep1)

Using the mentioned categories, we will define three different kinds of derived category:

- 1.  $D(\infty$ -Cat): Cat (the directed derived category of  $\infty$ -categories)
- 2.  $D(\infty$ -Grpd): Cat (the derived category of  $\infty$ -groupoids)
- 3.  $D(\infty\text{-Grpd}_0)$ : Cat (the derived category of based  $\infty$ -groupoids)

These are formed by identifying those morphisms ( $\infty$ -functors) between which there is a natural transformation.

We also create a second kind of category, one for each of the objects in the respective categories above:

- 1. For C :  $D(\infty$ -Cat), a category  $D(\infty$ -Cat/C) : Cat
- 2. For G :  $D(\infty\text{-Grpd})$ , a category  $D(\infty\text{-Grpd/G})$  : Cat
- 3. For  $G_0$  :  $D(\infty\text{-}Grpd_0),$  a category  $D(\infty\text{-}Grpd_0/G_0)$  : Cat

For the model built on simplicial sets,  $\vec{\Omega}$  will be representable by  $\Delta^1$  with respect to an internal hom, and  $\vec{\Omega}$  will be representable by a model of the unit interval I := [0,1].

The six mentioned internal structures are related to six functors:

- (I)  $\vec{\Omega}$ :  $\infty$ -Cat  $\longrightarrow \infty$ -Cat (notation for the directed path space functor, related to  $[\Delta^1,-]$ ).  $D(\vec{\Omega})$  factors through internal categories in  $D(\infty$ -Cat) by a categorical equivalence  $D(\infty$ -Cat)  $\cong$  IntCat  $D(\infty$ -Cat) (internal categories in  $D(\infty$ -Cat))
- (II)  $\vec{\omega}$  (1 C):  $\infty$ -Cat/C  $\longrightarrow \infty$ -Cat/C, the derived directed homotopy pullback with 1 C.  $D(\vec{\omega}$  (1 C)) factors through a categorical equivalence between  $D(\infty$ -Cat/C) and internal  $\vec{P}$ C-presheaves in  $D(\infty$ -Cat/C).
- (III)  $\vec{\Omega}: \infty\text{-Grpd} \longrightarrow \infty\text{-Grpd}$  (notation for the path space functor [I,-]), the derived homotopy pullback of an  $\infty$ -groupoid with itself.  $D(\vec{\Omega})$  factors through a categorical equivalence between  $D(\infty\text{-Grpd})$  and internal groupoids in  $D(\infty\text{-Grpd})$
- (IV)  $\vec{\omega}$  (1 X):  $\infty$ -Grpd/X  $\longrightarrow \infty$ -Grpd/X, the derived homotopy pullback with 1 X. D( $\vec{\omega}$  (1 X)) factors through internal  $\vec{P}$ X
- (V)  $\Omega: \infty\text{-}\mathrm{Grpd}_0 \longrightarrow \infty\text{-}\mathrm{Grpd}_0$ , the loop space functor.  $D(\Omega)$  factors through a categorical equivalence between  $D(\infty\text{-}\mathrm{Grpd}_0)$  and internal groups in  $D(\infty\text{-}\mathrm{Grpd}_0)$  (the loop space functor on connected based  $\infty$ -groupoids)
- (VI)  $\omega$  (1 X):  $\infty$ -Grpd $_0/X_0 \longrightarrow \infty$ -Grpd $_0/X_0$ , the homotopy pullback with the base of  $X_0$ . D( $\omega$  (1 X)) factors through internal PX $_0$ -actions in based connected spaces over  $X_0$ .

(v) in the above is shown here and (vi) in the above is shown in a typical treatment of G-principal bundles.

The functors  $\vec{\omega}$  (1 C),  $\vec{\omega}$  (1 X), and  $\omega$  (1 C) in the above ensue from a more general construction:

- 1. For C, D : D( $\infty$ -Cat), and f : C  $\longrightarrow$  D,  $\vec{\omega}$  f : D( $\infty$ -Cat/D)  $\longrightarrow$  D( $\infty$ -Cat/C) (derived directed homotopy pullback)
- 2. For B, E : D( $\infty$ -Grpd), and f : E  $\longrightarrow$  B,  $\vec{\omega}$  f : D( $\infty$ -Grpd/B)  $\longrightarrow$  D( $\infty$ -Grpd/E) (derived homotopy pullback)
- 3. For  $B_0$ ,  $E_0$ :  $D(\infty\text{-Grpd}_0)$ , and  $f: E_0 \longrightarrow B_0$ ,  $\omega f: D(\infty\text{-Grpd}_0/B_0) \longrightarrow D(\infty\text{-Grpd}_0/E_0)$  (homotopy pullback with the base)

These six factored functors  $\vec{P}$ ,  $\vec{P}$ ,  $P:D(\infty\text{-Grpd}_0)$ ,  $\vec{p}$  (1 C),  $\vec{p}$  (1 X), p are each fully faithful and produce categorical equivalences; we later construct functors  $\vec{B}$ ,  $\vec{B}$ ,  $\vec{B}$ ,  $\vec{b}$ ,  $\vec{b}$ , b defined on the essential image of these six, which are inverse to them up to natural isomorphism.

We obtain six categorical equivalences witnessed by these twelve functors (along with twelve natural isomorphisms). Here are the types of  $\vec{P}$ ,  $\vec{P}$ ,  $P:D(\infty\text{-Grpd}_0)$ ,  $\vec{p}$  (1 C),  $\vec{p}$  (1 X), p:

- 1. The directed path space, the path space, and loop space form components of the functors  $\vec{P}$ ,  $\vec{P}$ , and P, which are valued in internal categories, internal groupoids, and internal groups respectively.
  - (a)  $\vec{P}: D(\infty\text{-Cat}) \longrightarrow Cat \ D(\infty\text{-Cat})$
  - (b)  $\ddot{P}: D(\infty\text{-}Grpd) \longrightarrow Grpd \ D(\infty\text{-}Grpd)$
  - (c)  $P: D(\infty\text{-}Grpd_0) \longrightarrow Grp\ D(\infty\text{-}Grpd)$  (see here)
- 2. The directed homotopy pullback, the homotopy pullback, and the homotopy pullback with the base form components of the functors  $Alg(Mon(\vec{\omega}))$ ,  $Alg(Mon(\vec{\omega}))$ , and Alg(Mon(p)), respectively.
  - (a)  $\vec{p}$  (1 C): D( $\infty$ -Cat/C)  $\longrightarrow$  IntPrShf D( $\infty$ -Cat/C)  $\vec{\Omega}$ C
  - (b)  $\vec{p}$  (1 X): D( $\infty$ -Grpd/X)  $\longrightarrow$  IntAct D( $\infty$ -Grpd/X)  $\vec{\Omega}$ X
  - $\text{(c) } p \text{ (1) } X_0 \text{): } D(\infty\text{-}Grpd_0 \! / \! X_0) \longrightarrow IntAct_0 \text{ } D(\infty\text{-}Grpd_0 \! / \! X_0) \text{ } \Omega X_0$

Above, the functors  $\vec{P}$ ,  $\vec{P}$ ,  $\vec{P}$ ,  $\vec{P}$ ,  $\vec{p}$ , and  $\vec{p}$  feature  $\vec{\Omega}$ ,  $\vec{\Omega}$ ,  $\vec{\Omega}$ ,  $\vec{\omega}$ , and  $\vec{\omega}$  in their components, and can be related to them using constructions from Eilenberg-Moore theory.

These six new functors combine with the functors below to form categorical equivalences:

- 1. The directed homotopy colimit of a point with an internal category in  $D(\infty\text{-Cat})$  as a diagram, the homotopy colimit of a constant functor with an internal internal group as a diagram
  - (a)  $\vec{B}$ : essential\_image  $\vec{P} \longrightarrow D(\infty\text{-Cat})$
  - (b)  $\vec{B}$ : essential\_image  $\vec{P} \longrightarrow D(\infty\text{-Grpd})$
  - (c) B : essential\_image P  $\longrightarrow$  D( $\infty$ -Grpd<sub>0</sub>) (see here)
- 2. The clutching functors are inverse to the above functors up to natural isomorphism:
  - (a)  $\vec{b}$ : essential\_image  $\vec{p} \longrightarrow D(\infty\text{-Cat/C})$
  - (b)  $\vec{b}$ : essential\_image  $\vec{p} \longrightarrow D(\infty\text{-Cat/C})$
  - (c) b : essential\_image p  $\longrightarrow$  D( $\infty$ -Grpd<sub>0</sub>/X<sub>0</sub>)

As mentioned, we will show six categorical equivalences featuring these:

- 1.  $\vec{P} \bullet \vec{B} \cong \mathbb{1}$  (IntCat D( $\infty$ -Cat)) and  $\vec{B} \bullet \vec{P} \cong \mathbb{1}$  D( $\infty$ -Cat)
- 2.  $\vec{P} \bullet \vec{B} \cong \mathbb{1}$  (IntGrpd D( $\infty$ -Grpd)) and  $\vec{B} \bullet \vec{P} \cong \mathbb{1}$  D( $\infty$ -Grpd)
- 3.  $P \bullet B \cong \mathbb{1}$  (IntGrp  $D(\infty\text{-Grpd}_0)$ ) and  $B \bullet P \cong \mathbb{1}$   $D(\infty\text{-Grpd}_0)$  (see here)
- 4.  $\vec{p} \bullet \vec{b} \cong \mathbb{1}$  (IntPrShf D( $\infty$ -Cat/C)  $\vec{P}$ C) and  $\vec{b} \bullet \vec{p} \cong \mathbb{1}$  D( $\infty$ -Cat/C)
- 5.  $\vec{p} \bullet \vec{b} \cong \mathbb{1}$  (IntAct D( $\infty$ -Cat/C)  $\vec{P}X$ ) and  $\vec{b} \bullet \vec{p} \cong \mathbb{1}$  D( $\infty$ -Cat/C)
- 6.  $p \bullet b \cong \mathbb{1}$  (IntAct<sub>0</sub> D( $\infty$ -Grpd<sub>0</sub>/X<sub>0</sub>) PX<sub>0</sub>) and  $b \bullet p \cong \mathbb{1}$  D( $\infty$ -Grpd<sub>0</sub>/X<sub>0</sub>) (see here)

We will make extensive use of Mathlib's bicategory of categories and material on simplicial sets. We further use Mathlib's pullbacks and categorical products, as well as their Eilenberg-Moore theory constructions. I'd like to extend my appreciation to Scott Morison, Eric Wieser, Floris Van Doorne, and all the contributors who have put their efforts into creating these robust features for Mathlib 4.

Altogether, the project gets the following "periodic table" of 24 functors featured on the front cover:

$ exttt{D}(\infty exttt{-Cat})$	$\vec{\Omega}$	$\vec{P}$	$\vec{\mathrm{B}}$	Ē	$\mathtt{D}(\infty ext{-Cat/C})$	$\vec{\omega}$	b	$\vec{p}$	ē
$\mathtt{D}(\infty ext{-Grpd})$	Ω	P	$\ddot{\mathrm{B}}$	É	D(∞-Grpd/G)	$\vec{\omega}$	b	ÿ	ë
$D(\infty\text{-Grpd}_0)$	Ω	P	В	Е	$D(\infty-Grpd_0/G_0)$	$\omega$	b	p	e

Here are the names of the symbols featured above:

Deductive Remembrant		Delooping	Free
$\vec{\Omega}$ (Directed path space)	$ec{P}$ (Remembrant derived directed path space)	$\vec{B}$ (Classifying space for internal categories)	Ē
$\vec{\Omega}$ (Path space)	$\overrightarrow{P}$ (Remembrant derived path space)	B (Classifying space for internal groupoids)	Ë
Ω (Loop space)	P (Remembrant derived loop space)	B (Classifying space for internal groups)	Е
$ec{\omega}$ (Directed homotopy pullback)	$ec{p}$ (Remembrant derived directed homotopy pullback)	$\vec{b}$ (Classifying space for internal presheaves)	ē
$\overset{\leftrightarrow}{\omega}$ (Homotopy pullback)	$\overrightarrow{p}$ (Remembrant derived homotopy pullback)	$\vec{b}$ (Classifying space for internal groupoid actions)	ë
$\omega$ (Homotopy fiber)	p (Remembrant derived homotopy fiber)	b (Classifying space for internal group actions)	e

The term "remembrant" in the above is not common terminology. It is intended to mean that the second collumn features functors which are valued in categories of internal objects wheras the left collumn forms particular components of those structures.

The notation here is both an attempt to make the various analogies manifest while sticking to familiar notation where available (such as in the case of  $\Omega$  and B, which match the ordinary usage of these symbols). In the above, P could be said to stand for "(remembrant) path space" and p for "(remembrant) pullback", while at the same time this matches a nice theme that our capitcal letters reflect various internal structures and their lower-case forms reflect the corresponding actions.

The mentioned "delooping principals", which identify categories which are internal X's in themselves, form important consequences of the three Whitehead theorems. All in all, there are twelve important theorems we will show:

#### Twelve Goals

- (I) Define and inhabit the whitehead\_theorem\_for\_categories : Type.
- (II) Define the Puppe sequence for  $\infty$ -categories and prove its exactness.
- (III) Define and inhabit the internal\_category\_delooping\_principal : Type.
- (IV) Define and inhabit the internal\_sheaf\_delooping\_principal : Type.
- (V) Define and inhabit the whitehead\_theorem\_for\_groupoids : Type.
- (VI) Define the Puppe sequence for  $\infty$ -groupoids and prove its exactness
- (VII) Define and inhabit the internal groupoid\_delooping\_principal: Type.
- (VIII) Define and inhabit the internal\_groupoid\_action\_delooping\_principal: Type.
  - (IX) Define and inhabit the whitehead theorem: Type.
  - (X) Define the Puppe sequence for based connected  $\infty$ -groupoids and prove its exactness
  - (XI) Define and inhabit the internal group\_delooping\_principal: Type.
- (XII) Define and inhabit the internal group action delooping principal: Type.

None of these theorems are currently contained in Mathlib. The last four are famously known as:

- 1. The Whitehead theorem
- 2. The Puppe sequence and its exactness
- 3. The theorem that  $\Omega \bullet B \cong \mathbb{1}$  (IntGrp D( $\infty$ -Grpd)) and B  $\bullet \Omega \cong \mathbb{1}$  D( $\infty$ -Grpd<sub>0</sub>)
- 4. The theorem that BG classifies G-principal bundles

#### 3. Introduction to Lean 4

The main way to tell Lean 4 what something means is with def, which defines a term in dependent type theory. Much in the same way as other computer languages, we then supply the type of the term (e.g. Int for integer), followed by the formula itself:

```
Lean 1

def zero : Nat := 0
```

Here we have introduced a natural number n using the type Nat that comes with Lean 4.

As a beginner, it's normal to take some time to get comfortable with Lean and formal proof systems. It's a journey that requires practice and patience. Lean has an active community that provides support and resources to help you along the way.

Constituents of x, y: X of types X can also stand to be equal or unequal, written x = y, and it is the properties of equality which in addition to the dependent type theory make a type behave like a set. Equality satisfies the three properties of an equivalence relation, which we cover presently. Consider first the reflexivity property of equality:

This command defines a function called reflexivity that proves the reflexivity property of equality. The function takes two type parameters: X represents the type of the

elements being compared, and x represents an element of type X. It also takes an argument  $\omega$  which is a proof that x is equal to itself (x = x). The function body states that the result of reflexivity is the proof  $\omega$  itself using the Eq.refl constructor, which indicates that x is equal to itself.

In Lean 4,  $\{x : X\}$  represents an implicit argument, where Lean will attempt to infer the value of x based on the context. (x : X) represents an explicit argument, requiring the value of x to be provided explicitly when using the function or definition.

This command defines a function called symmetry that proves the symmetry property of equality. It takes three type parameters: X represents the type of the elements being compared, and x and y represent elements of type X. The function also takes an argument  $\omega$  which is a proof that x is equal to y (x=y). The function body states that the result of symmetry is the proof  $\omega$  itself using the Eq. symm constructor, which allows you to reverse an equality proof.

This command defines a function called transitivity that proves the transitivity property of equality. It takes four type parameters: X represents the type of the elements being compared, and x, y, and z represent elements of type X. The function also takes two arguments p and q. p is a proof that x is equal to y (x = y), and q is a proof that y is equal to z (y = z). The function body states that the result of transitivity is the proof of the composition of  $\omega$  and q using the Eq. trans constructor, which allows you to combine two equality proofs to obtain a new one.

These Lean commands define functions that prove fundamental properties of equality: reflexivity (every element is equal to itself), symmetry (equality is symmetric), and transitivity (equality is transitive). These properties are essential for reasoning about equality in mathematics and formal proofs.

We must also require that functions satisfy extensionality:

Extensionality, a key characteristic of sets and types, asserts that functions which are equal on all values are themselves equal, and it is featured prominently in what is perhaps the most well known mathematical foundations of ZFC.

There are several other features of equality with respect to functions which we should be aware of:

```
Lean 6

def equal_arguments \{X : Type\} \{Y : Type\} \{a : X\} \{b \rightarrow : X\} (f : X \rightarrow Y) (p : a = b) : f a = f b :=  \rightarrow congrArg f p

def equal_functions \{X : Type\} \{Y : Type\} \{f_1 : X \rightarrow Y\} \{f_2 : X \rightarrow Y\} \{p : f_1 = f_2\} \{x : X\} \{f_1 : X \rightarrow Y\} \{f_2 : X \rightarrow Y\} \{f_1 : f_2\} \{f_1 : X \rightarrow Y\} \{f_2 : X \rightarrow Y\} \{f_1 : f_2\} \{f_2 : f_2\} \{f_1 : f_2\} \{f_1 : f_2\} \{f_2 : f_2\} \{f_2 : f_2\} \{f_2 : f_2\} \{f_1 : f_2\} \{f_2 : f_2\} \{f
```

The tutorial here provides a good introduction to using the dependent type theory in Lean.

#### 4. Unicode

#### Here is a list of the unicode characters we will use:

Symbol	Unicode	VSCode shortcut	Use

Of these, the characters ,,,,,,, and  $\leftrightarrow$  do not have VSCode shortcuts, and so we provide alternatives for them.

It is not possible to copy the from the pdf to the clipboard while preserving the integrity of the code. To see the official Lean 4 file please click the link on the top right of the front page or this.

The conceptual difference between the first, second, and third Whitehead theorems.

# Chapter 1: Mathlib's Category Theory Section

I intend for this to cover some of the basics of Mathlib's category theory in the final document. For now, just know that we'll be using bicategories, the bicategory of categories, Cat, Functor, NaturalTransform, its Eilenberg-Moore theory constructions, and its material on simplicial sets.

## 5. Mathlib's Category, Functor, NaturalTransform

Here I intend to cover some of the basics of Mathlib's Categories, Functors, and NaturalTransformations. I will for instance write out checks (#check) of the main types, as well as some instructions as to how to create new examples of these structures for beginners.

#### 6. Mathlib's bicategories

Even though we are only going to use strict bicategories, strict bicategories work terribly with type systems and necessitate the use of cast. Mathlib's bicategories are also enabled by aesop, which plays a nice role in inferring simple lemmas such as ones involving identity and associativity laws. The bicategory of categories is the only bicategory we'll really need, if at all.

#### 7. Mathlib's adjunctions, monads, and comonads

We're going to make extensive use of adjunctions, specifically the ones involved in directed homotopy pullback, homotopy pullback, and homotopy kernel. These are each adjoint to a functor which post-composes with a morphism.

We will also make a lot of use of monads and comonads.

#### 8. Mathlib's Eilenberg-Moore theory

Mathlib has great constructions of the fundamentals in Eilenberg-Moore theory. It turns out that we'll not actually use any co-Eilenberg co-Moore theory. We'll make use of:

- 1. The monad corresponding to an adjunction
- 2. The adjunction corresponding to a monad (Eilenberg-Moore adjunction)

#### 9. Mathlib's pullbacks and products

Pullbacks and products are essential to the definition of the internal structures we're using. For our purposes, it makes the most sense to define pullbacks in a way which handles the assumption of their existence pleasently (and without much work for the user).

In the material that follows, we will be interested in forming pullbacks for four of the six internal structures that we make. We also take care to establish the definition of a delooping of an endofunctor of Bicategory.Cat (Mathlib's category of categories).

#### 10. Mathlib's simplicial sets

Mathlib already has simplicial sets, along with the the definition of the n-simplices  $\Delta^n$  and the inner horns  $\Lambda[:]$ . We

1. Mathlib's definition of  $\Delta^n$ 

```
Lean 7

-- #check \Delta^n
/-

Goal: check Lean's n-simplices and
-/
```

2. Mathlib's definition of the inner horns

```
Lean 8
-- #check ???
```

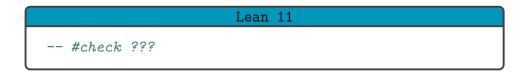

3. Mathlib's definition of the inclusion of inner horns

```

#check	\$\$\$	

PART 1:  $\infty ext{-CATEGORIES}$ 

# Chapter 2: $\infty$ -Cat

This chapter and the next chapter are more technical and difficult than the rest of the book.

- 1. Defining  $D(\infty$ -Cat) by formally inverting weak equivalences.
- 2. Defining  $D(\infty\text{-Cat/C})$  by formally inverting weak equivalences.
- 3. Defining a fibrant replacement functor for  $\infty$ -Cat
- 4. Defining a fibrant replacement functor for  $\infty$ -Cat/C
- 5. We first construct both the category  $D(\infty\text{-Cat})$  and, for each  $C:D(\infty\text{-Cat})$ , the category  $D(\infty\text{-Cat}/C)$  by formally inverting weak equivalences in the category of quasicategories and the category of quasicategories over C.

Our choice of symbols refects our choice of three variations of the Whitehead theorem and three Puppe sequences.  $\vec{\Omega}$ , the analogue of loop space, is the internal hom functor  $[\Delta^1,-]:\infty$ -Cat  $\longrightarrow \infty$ -Cat. This is not hard to construct, with the main lemma being that the path space of a quasicategory has the quasicategory lifting conditon.

We will be interested in one formal model of  $D(\infty\text{-Cat})$  which consists of formal compositions  $f_1 \bullet g_1 \bullet f_2 \bullet g_2 \bullet \boxed{?} \bullet f_n \bullet g_n$ , where  $g_n : Dom(f_{n+1}) \longrightarrow ???$  is a weak equivalence, and something similar for  $D(\infty\text{-Cat})$ . However, it is still vital to have the replacement functor repl, which ensures the Whitehead theorem for particular  $\infty$ -categories which are constructed out of attaching maps.

 $\vec{\Omega}$  is to internal categories as  $\vec{\omega}$  is to internal C-presheaves. It is also called directed homotopy pullback. These functors will later be used to produce functors  $\vec{P}: D(\infty-\text{Cat}) \longrightarrow \text{IntCat } D(\infty-\text{Cat})$  and  $\vec{p}: D(\infty-\text{Cat/C}) \longrightarrow \text{IntPrShf}(\vec{P} \ C) \ D(\infty-\text{Cat/C})$ .

## 13. $\pi_n$

The mentioned functors  $\vec{\pi}_n$  are designed with both Whitehead theorem (a) and Puppe sequence (a) in mind.

# Chapter 3: The Whitehead Theorem for $\infty ext{-Categories}$

In this chapter, we take on the objective of Whitehead theorem (a), out of which we will prove the other more concrete Whitehead theorems:

$$\forall (\text{E:D}(\infty\text{-Cat})), \forall (\text{B:D}(\infty\text{-Cat})), \forall (\text{F:E} \longrightarrow \text{B}), \forall (\text{G:E} \longrightarrow \text{B}), (\forall (\text{n:Nat}), (\vec{\pi}_n \text{ F} = \vec{\pi}_n \text{ G})) \\ \longrightarrow \text{F} = \text{G}$$

We can attempt to form a slightly different category, much like the above, called  $\mathcal{D}(\infty\text{-Cat})$ , at first, and in a formal way, so as to create a category whose object component  $\mathcal{D}(\infty\text{-Cat})$ . $\alpha$  matches the object component  $\infty\text{-Cat}$ . $\alpha$  while featuring the above theorem in a formal way. However, with this as our model of  $D(\infty\text{-Cat})$ , we may then also be interested in the establishment of a model in which the Whitehead theorem is demonstrated, with the main idea being to prove two complementary concepts:

- 1. (REP) Establish a kind of "weak equivalent fibrant replacement"  $R:\infty\text{-Cat}.\alpha\longrightarrow\infty\text{-Cat}.\alpha$  (. $\alpha$  gives the object component in Mathlib's category theory library), analogous to CW-complex replacement in Whitehead's original paper. It's especially nice if R forms the object component of a functor  $F:\infty\text{-Cat}\longrightarrow\infty\text{-Cat}$ .  $D(F):D(\infty\text{-Cat})\longrightarrow D(\infty\text{-Cat})$  should be a categorical equivalence, and that is what we will do.
- 2. (HEP) For the object R X, demonstrate that any F,G:  $(R X) \longrightarrow Y$  such that  $\forall (n:Nat), (\vec{\pi}_n F = \vec{\pi}_n G)$ , there is a directed homotopy equivalence between F and G. Note that "directed homotopy equivalence" consists of a composible sequence of simple directed homotopies H?:  $\Delta^1 \times (R X) \longrightarrow Y$ , 1? in the even H? running reverse to the odd H?.

Both of these will use induction on Lean's Nat. The first of these could be called a REP (for REplacement Property, but this isn't usual terminology), and the second typically uses induction and a HEP (Homotopy Extension Property). Our REPa will consist of objects made out of particular kinds of pushouts called attaching maps, and can be made functorial. Proving the HEPa can be done by well-order induction on the attaching maps present in our choice of R, thereby reducing to the case of extending

a homotopy along a single attachment.

Our HEPa (directed box filling) is similar to the HEP shown in Whitehead's original paper, and to the approach detailed in Hatcher's textbook, though no doubt modified to suit our two goals:

- (I) The analogue of the Puppe sequence on the front cover needs to hold.
- (II) The first Whitehead theorem on the front cover needs to hold.

These two considerations determine our choice of  $\vec{\pi}_n$ ,  $\vec{\Omega}$ , and  $\vec{\omega}$ . We take  $\vec{\Omega}$  to be (simply) the internal hom functor  $[\Delta^1, -]$  (which requires showing that  $\vec{\Omega}X$  has the inner-horn filling condition).  $\vec{\omega}$  is then defined as a certain pullback of  $\vec{\Omega}$ , and  $\vec{\pi}_n$  is designed to produce a Puppe sequence with a meaningful notion of exactness by which we can demonstrate the goal of delooping principals (i) and (ii). Specifically, it makes sense to use cubes in our definition of  $\vec{\pi}_n$  because of how they are representing objects of  $\vec{\Omega}^n$ . Meanwhile, it is also clear that the quotient producing  $\vec{\pi}_n$  is subtle in exactly how it requires fixing the endpoints of a sequence of alternating directed homotopies. We will define  $\vec{\pi}_n$ 's by identifying those objects x, y:  $\vec{\Omega}^n$  X which are homotopic by a homotopy which restricts to a constant along the face maps  $\mathbf{f}[?]: \vec{\Omega}^{n-1}$  X  $\longrightarrow \vec{\Omega}^{n-1}$  X (which correspond to pairs (n,b), where b: Bool).

Imagine for a moment the picture of a square shaped cusion; we might make such a cusion by first soeing together 6 squares of cloth and filling it with material, then "soeing the walls down to a square". Here we go with this:

- 1. Define a n-cubical cusion using the boundary of an n-1 cube times  $\Delta^1$ , i.e. the quotient of  $(\Delta^1)^{n-1} \times \Delta^1$  by an equivalence relation, but we have to start our model somewhere), or perhaps more easily the pushout of  $f: \Delta^1 \times (\partial((\Delta^1)^n)) \longrightarrow (\Delta^1)^{n+1}$  by the projection map  $\Delta^1 \times (\partial((\Delta^1)^n)) \longrightarrow \partial((\Delta^1)^n)$
- 2. Define a simplicial cusion using the boundary of an n-1 simplex times  $\Delta^1$ , i.e. the quotient of  $(\Delta^1)$  by an equivalence relation, or perhaps more easily the pushout of  $f: \Delta^1 \times (\partial(\Delta^n)) \longrightarrow (\Delta^1) \times \Delta^n$  by the projection map  $\Delta^1 \times (\partial((\Delta^1)^n)) \longrightarrow \partial(\Delta^n)$

The boundary of a cusion is a pouch, isomorphic to a pushout of two cubes glued together at their boundaries:

- 1. Define a n-cubical pouch as the pushout of two boundary maps  $\partial((\Delta^1)^n) \longrightarrow (\Delta^1)^n$
- 2. Define a simplicial pouch as the pushout of two boundary maps  $\partial(\Delta^n) \longrightarrow \Delta^n$

Notice that paths in  $\vec{\Omega}^n X$  produce paths in  $\vec{\Omega}^{n-1} X$  in as many ways as there are face maps  $(\Delta^1)^{n-1} \longrightarrow \Delta^{1n}$ , these could be called restrictions and are no doubt related to the pouches and cusions we just defined. The cartesian closed structure on simplicial sets with the lifting condition clarifies the relationship between the two available definitions of  $\vec{\pi}_n$ :

- 1. Homotopies of maps from a cube which are constant on the boundary
- 2. Paths of maps in  $\vec{\Omega}^{n-1}X$  which produce constant maps under the mentioned restritions.
- 3. Maps from a pouch mod an equivalence relation (really we phrase this as a pushout!), namely the equivalence relation in which any two maps from a pouch that extend to maps from a cusion are identified.

After we construct  $\vec{\pi}_n$  in the first section, we will be in a place to demonstrate that the natural transformation weak\_equivalence : repl  $\longrightarrow$  (1  $\infty$ -Cat) consists of weak equivalences (a fact which we call REP, which is short for REplacement Principal). This is covered in the section titled REP, which also constructs repl and weak\_requivalence.

In sum, the goal of the present chapter is to use similar insights to the proof of the Whitehead theorem featured Hatcher's textbook to prove Wa and Pa for the model of quasicategories, using Mathlib's predefined horns and simplices in its simplicial sets section. The main difference is that our work must take care to respect the directed nature of quasicategories.

1. Defining repl

2.

#### 14. REP

We have divided the work of proving Whitehead theorem (a) into two steps: REP and HEP. In this section, we construct a functor repl:  $\infty$ -Cat  $\longrightarrow \infty$ -Cat along with a natural transformation weak\_equivalence: repl  $\longrightarrow$  (1  $\infty$ -Cat). To construct repl

Consider the context of , supposing that we have constructed a homotopy ... This gives a picture that is a bit like "filling up a jar": a homotopy h: of f, g:  $\partial\Delta^2\longrightarrow Y,$  along with the value of g on  $\Delta^2,$  produces a "jar" shape in Y, which can be "filled up" to produce a homotopy h:  $\Delta^1\times\Delta^2\longrightarrow Y.$  This is easier for simplicial-based approaches than for point-set topological approaches, the latter of which needs extra steps that deform a map into a cellular map.

This construction, in the case of point set topology, often involves first deforming maps so as to be cellular; however our analogue of CW complexes allows us to skip this step.

This construction (HEP for quasicategories) may even be equivalent to the quasicategory lifting condition if we are lucky. It is also the main technical device allowing for our concrete choice of model (quasicategories).

In this section, we demonstrate this extension property and use it to conclude the Whitehead theorem for  $\infty$ -categories stated above.

Directed Prism Filling (DPF) Let Y be a quasicategory, and let f, g:  $\partial \Delta^n \longrightarrow Y$ . A homotopy h:  $\partial \Delta^n \times \Delta^1 \longrightarrow Y$  between f, g:  $\partial \Delta^n \longrightarrow Y$  extends to a map H:  $\Delta^n \times \Delta^1 \longrightarrow Y$ ; this follows from the condition that Y be a quasicategory. H(-,1) and g match on  $\partial \Delta^n$ , producing a map f: X  $\longrightarrow Y$ , where X consists of two copies of  $\Delta^n$  glued together at the boundary. Consider a space X' formed as a quotient of  $\Delta^n \times \Delta^1$  by  $\partial \Delta^n \times \Delta^1$ . There is a map  $\phi: X \longrightarrow X$ . An induction hypothesis on f and g involving  $\pi_n$  ensures that the aparent map  $X \longrightarrow Y$  lifts along  $\phi$ , producing a map from  $\Delta^n \times \Delta^1$  which is constant on  $\partial \Delta^n \times \Delta^1$ . Stacking this on top of H can be done using an isomorphism between  $\Delta^1$  and  $\Delta^1$  glued with itself along different endpoints. Altogether this produces a homotopy between f and g.

Directed prism filling may combine fruitfully with the yoneda lemma and/or the fact that simplicial sets are determined by the sets  $[\Delta^n, X]$  along with combinatorial information (face and degeneracy maps).

Decomposing  $\Delta^{\mathbf{n}} \times \Delta^{\mathbf{1}}$  into a colimit involving n+1  $\Delta^{n+1}$ 's ...

In the above, it may be easier if we make use of sub-simplicial sets and prove the theorem using that colimit applied to a natural isomorphism of diagrams products an

isomorphism.

The decomposition

A definition of  $\vec{\pi}_n$  which is consistent with our goals of Wa and Pa is one as a certain pushout involving  $(\vec{\Omega}^n X)$ — one which amounts to taking an equivalence relation by paths in  $\vec{\Omega}^n X$  which restrict to constant paths along the face maps  $f[:\vec{\Omega}^{n-1} X \to \vec{\Omega}^n X]$ . Here,  $\vec{\Omega}$  is easy to define in the model of quasi-categories, and it amounts . Besides fullfilling our goal of the first Whitehead theorem and puppe sequence, this definition of  $\vec{\pi}_n$  strikes me as elegant because it uses all of the ways for  $\vec{\Omega}^n X$  to map into  $\vec{\Omega}^{n+1} X$ .

The next symbols in the project's "periodic table" that we construct, after  $\vec{\Omega}$  and  $\vec{\pi}_n$ , will be  $\vec{B}$  and  $\vec{E}$ , which we feature in the chapter on Puppe sequence (a).

A useful thing for us to construct first is the boundary of a product of  $\Delta^1$ 's and the boundary of a directed simplex. We might even like to expand on this later, but for now just consider for a moment how each might be made out of a glueing construction involving face maps.

Even though the  $\vec{\pi}_n$ 's can be defined using  $\vec{\Omega}^n$  X and various face maps  $f_n(n,b)$ :  $\vec{\Omega}^{n-1}$  X  $\longrightarrow \vec{\Omega}^n$  X for  $b:\{0,1\}$ , it may be nice to have this as a result, with the definition one featuring two cubes glued together along their boundary.

This means that we want directed box filling in addition to directed prism filling (but which also uses directed prism filling in its proof).

Directed Box Filling (DBF) Let Y be a quasicategory, and let f, g:  $\partial \Delta^n \longrightarrow Y$ . A homotopy h:  $\partial \Delta^n \times \Delta^1 \longrightarrow Y$  between f, g:  $\partial \Delta^n \longrightarrow Y$  extends to a map H:  $\Delta^n \times \Delta^1 \longrightarrow Y$ ; this follows from the condition that Y be a quasicategory. H(-,1) and g match on  $\partial \Delta^n$ , producing a map f: X  $\longrightarrow Y$ , where X consists of two copies of  $\Delta^n$  glued together at the boundary. Consider a space X' formed as a quotient of  $\Delta^n \times \Delta^1$  by  $\partial \Delta^n \times \Delta^1$ . There is a map  $\phi: X \longrightarrow X$ . An induction hypothesis on f and g involving  $\pi_n$  ensures that the aparent map X  $\longrightarrow Y$  lifts along  $\phi$ , producing a map from  $\Delta^n \times \Delta^1$  which is constant on  $\partial \Delta^n \times \Delta^1$ . Stacking this on top of H can be done using an isomorphism between  $\Delta^1$  and  $\Delta^1$  glued with itself along different endpoints. Altogether this produces a homotopy between f and g.

This goes hand-in-hand with a definition of  $\vec{\pi}_n$  which suits (I) and (II) in the introduction to chapter (3). If we make sure to prove lemmas...

The box filling and prism filling HEPs can be extended to the case of attaching all cells of a particular fixed dimension and as indexed by simplicial set arising from a set (or Lean 4 Type). That is, we might like to extend  $\times$  () (or possibly somehow a Set as well), and that we may find an interest in the following two definitions of  $\vec{\pi}_n$ , which

are designed to fullfill both (I) and (II) in the chapter's introduction.

Breaking down DBF further can be done conveniently using sub-simplicial sets, just like we used in the proof of prism filling.

Decomposing  $(\Delta^1)^n$  into a colimit involving n!  $\Delta^n$ 's Consider the face maps f?:  $\Delta^n \longrightarrow \Delta^{n+1}$ 

The decomposition The box filling lemma allows us to prove HEP:

#### 16. The Whitehead Theorem for $\infty$ -Cat

The HEP in the last

..H(-,1) and g match on  $\partial \Delta^n$ , producing a map  $f: X \longrightarrow Y$ , where X consists of two copies of  $\Delta^n$  glued together at the boundary. Consider a space X' formed as a quotient of  $\Delta^n \times \Delta^1$  by  $\partial \Delta^n \times \Delta^1$ . There is a map  $\phi: X \longrightarrow X$ '. An induction hypothesis on f and g involving  $\pi_n$  ensures that the aparent map  $X \longrightarrow Y$  lifts along  $\phi$ , producing a map from  $\Delta^n \times \Delta^1$  which is constant on  $\partial \Delta^n \times \Delta^1$ . Stacking this on top of H can be done using an isomorphism between  $\Delta^1$  and  $\Delta^1$  glued with itself along different endpoints. Altogether this produces a homotopy between f and g.

## Chapter 4: Internal categories and internal presheaves

In this chapter, we discuss internal categories and internal presheaves in a pull-back system. We may keep in mind that internal categories and internal presheaves can be formed in any category with pullbacks, even though we focus on the case of pullback systems because of our interest in Whitehead theorem (a).

After defining the category of internal categories  $D(\Gamma)$ , we proceed to observe how, for C,  $D:D(\Gamma)$ ,  $F:C\longrightarrow D$ ,  $(\vec{\omega}\ F)$ .obj F forms an internal categry. Further, in considering internal  $(\vec{P}_{-}(\Gamma)\ F)$ -presheaves for C,  $D:D(\Gamma)$ ,  $F:C\longrightarrow D$ , we proceed to make observations about  $(\vec{\omega}\ F)$ .obj G.

Section	Description
IntCat Γ : Cat	Internal categories
IntPrShf Γ C : Cat	Internal C-presheaves
The internal category principal	f ×_(B) f forms an internal category
The internal presheaf principal	f ×_(B) f forms an internal presheaf
$\vec{P}$ C : IntCat D( $\infty$ -Cat)	$\vec{\Omega}$ C forms a component of an internal category
$\vec{p}$ (1 C) D : IntPrShf D( $\infty$ -Cat/C) ( $\vec{P}$ C)	$\vec{\omega}$ (1 C) D forms a component of an internal C-presheaf

#### 17. IntCat $\Gamma$

In this chapter I define an internal category. Internal categories are most commonly defined on categories with enough pullbacks, but here I may also like to keep in mind that it is valuable to be able to iterate IntCat in the way of composition.

```
Lean 25

-- definition of an internal category in a pullback

-- system

/-

structure internal_category (\Gamma : Cat) where

Obj : .Obj

Mor : .Obj

Dom : .Hom Mor Obj

Cod : .Hom Mor Obj

Idn : .Hom Obj Mor

Fst : .Cmp Obj Mor Obj Idn Dom = \mathbb{1}_{-}(\Gamma.Obj) Obj

Snd : .Cmp Obj Mor Obj Idn Cod = \mathbb{1}_{-}(\Gamma.Obj) Obj

-- Cmp : D(\Gamma).\Gamma.PulObj ...

-- Id<sub>2</sub> : D(\Gamma).

-- Ass : D(\Gamma).
```

The internal functor structure combines with the internal category structure to give a category of internal categories in a pullback system.

# Lean 26 -- definition of an internal functor in a pullback system structure internal\_functor ( $\Gamma$ : pullback\_system) ( $\Gamma$ : internal\_category $\Gamma$ ) ( $\Gamma$ : internal\_category $\Gamma$ ) where Obj : D( $\Gamma$ ). Next we approach the internal category principal and internal presheaf principals, which concern how (directed) homotopy pullback can produce internal categories and internal presheaves.

#### 19. The Internal Category Principal

In this section we mention the internal category principal, which says that the pull-back of any morphism with itself forms a component of an internal category in any category in which this pullback exists. In fact, the most general form of the theorem works for a noncommutative analogue of pullback.

#### 20. The Internal Presheaf Principal

Next we mention the internal presheaf principal, which says that the pullback of any morphism with another forms a component of an internal presheaf in any category with pullbacks. Just as is the case for the last theorem, the most general form of this idea works for non-commutative analogues of pullback, wheras the case of pullback gives an internal groupoid action.

In this section, we construct the functor  $\vec{P}$  mentioned in the introduction. Specifically,  $(\Omega \ f)$  forms a component of an internal category.

Later we will add a theorem to the effect that  $\vec{P}$  as constructed is naturally isomorphic to a functor constructed using Eilenberg-Moore operations (speficially the structure $\Omega$  map of the Eilenberg-Moore category of a monad corresponding to  $\vec{\Omega}$ ).

-/
```

## Chapter 5: The Puppe Sequence for $\infty ext{-Categories}$

In this chapter we construct the Puppe sequence for  $\vec{\pi}_n$ . Note: one joint in this exact sequence consists not of a map but an action.} This will be used in the next chapter two establish two of the six categorical equivalences.

## Chapter 6: The Categorical Equivalences Involving B and b

After the construction in chapter 11, we will prove the internal category delooping principal, which is the first categorical equivalence of the six mentioned in the introduction. We also prove in this chapter the internal C-presheaf delooping principal, which is the second categorical equivalence of the six mentioned in the introduction. To do this, we first define  $\vec{B} = \vec{B}_{-}(\infty - \mathbb{Col})$  and  $\vec{b} = \vec{b}_{-}(\infty - \mathbb{Col})$ .

This much may be possible for the case of simplicial sets using first the construction of  $\vec{E}$  as a directed homotopy colimit (we can use Mathlib's geometric realization), and then quotienting by an apparant action of a particular internal category.

#### 23. B

```
Lean 57

-- def B : (Cat.Hom Cat_(\infty-Col) D(\infty-Col)).Obj := \rightarrow sorry
```

The b symbol formally gives a pseudofunctor, but we can also create a model in which it is a functor. It occurs as one side of a categorical equivalence, the second of the six categorical equivalences called "delooping principals".

```
Lean 59

-- notation "b" => Par
```

#### 25. The B-P Equivalence

The internal category delooping principal will look something like this:

```
Lean 60

-- def internal_category_delooping_principal : Type
\Rightarrow := D(\infty - \mathbb{C}_0 \mathbb{t}) \simeq (DeloopableIntCat \ D(\infty - \mathbb{C}_0 \mathbb{t}))
```

It should be readily available from the construction in the last chapter.

```
Lean 61

/-

-- def internal_category_delooping_principal_proof

∴ : internal_category_delooping_principal := {Fst}

∴ := internal_category_delooping_principalFst,

∴ Snd :=

∴ internal_category_delooping_principalSnd, Id₁

∴ := internal_category_delooping_principalId₁,

∴ Id₂ :=

∴ internal_category_delooping_principalId₂}

-/
```

#### 26. The b-p Equivalence

The internal presheaf delooping principal consists of a categorical equivalence between  $D(\infty\text{-Cat/C})$  and internal C-presheaves in  $D(\infty\text{-Cat/C})$ .

```
Lean 62

/-

def internal_presheaf_delooping_principal (C: D(\infty - \mathbb{C} \mathbb{O} \mathbb{D})): Type := Shf_(\infty - \mathbb{C} \mathbb{O} \mathbb{D})

P(X) = P(X)
```

Next we prove the internal C-sheaf delooping principal. This says says that  $Shf_(\infty-\mathbb{C}_0\mathbb{L})$  (P\_( $\infty-\mathbb{C}_0\mathbb{L}$ ) C C (1\_(D( $\infty-\mathbb{C}_0\mathbb{L}$ )) C))  $\simeq$ \_(Cat) !? (p\_( $\infty-\mathbb{C}_0\mathbb{L}$ ) C C (1\_(D( $\infty-\mathbb{C}_0\mathbb{L}$ )) C)).

```
Lean 63

-- The internal C-sheaf delooping principal
/-

def internal_presheaf_delooping_principal_proof (C
\Rightarrow : D(\infty - \mathbb{Col}).0bj):
\Rightarrow internal_presheaf_delooping_principal <math>C := \{Fst := internal_presheaf_delooping_principalFst,
\Rightarrow Snd :=
\Rightarrow internal_presheaf_delooping_principalSnd, Id_1
\Rightarrow := internal_presheaf_delooping_principalId_1,
\Rightarrow Id_2 :=
\Rightarrow internal_presheaf_delooping_principalId_2}
\Rightarrow internal_presheaf_delooping_principalId_2}
```

PART 2:  $\infty$ -GROUPOIDS

#### Chapter 7: $\infty$ -Grpd

In this section we establish the categories  $D(\infty\text{-Grpd})$  and  $D(\infty\text{-Grpd}/G)$  for  $G:D(\infty\text{-Grpd})$  out of the previous constructions. Our model for these categories is directly based on Mathlib's category of simplicial sets with the Kan lifting condition.

## Lean 64 --def derived\_category\_of\_infinity\_groupoids : Cat ∴ := sorry

```
Lean 65

/-
notation for D(\infty\text{-Grpd})
-/
```

```
Lean 66

--def derived_category_of_infinity_groupoids_over (G : D(\infty\text{-Grpd})) : Cat := sorry
```

```
Lean 67

/-
notation for D(\infty\text{-Grpd/G})
-/
```

## Chapter 8: The Whitehead Theorem for $\infty ext{-Groupoids}$

In this section, we prove Whitehead theorem (b), which says that  $\forall (E:D(\infty\text{-Grpd})), \forall (B:D(\infty\text{-Grpd})), \forall (F:E \longrightarrow B), \forall (G:E \longrightarrow B), (\forall (n:Nat), (\vec{\pi}_n \ F = \vec{\pi}_n \ G)) \longrightarrow F = G$ , where  $\vec{\pi}_n$  is notation for  $\vec{\pi}$  n.

The main idea here is to treat this by induction, extending a homotopy for each n to a homotopy for n+1. This gives a picture that is a bit like "filling up a jar": a homotopy  $h: I \times \partial \Delta^2$  of f,  $g: \partial \Delta^2 \longrightarrow Y$ , along with the value of g on  $\Delta^2$ , produces a "jar" shape in Y, which can be "filled up" to produce a homotopy  $h: I \times \Delta^2 \longrightarrow Y$ . This is easier for simplicial-based approaches than for point-set topological approaches, the latter of which needs extra steps that deform a map into a cellular map.

Mathlib also features cubes and their boundaries.

Alternatively, we can probably use the homotopy extension property shown for quasicategories in the first place, thereby recycling old work.

#### 27. HEP for $\infty\text{-groupoids}$

In this section, we demonstrate this extension property and use it to conclude the Whitehead theorem for  $\infty$ -categories stated above, using the previously constructed simplicial set based model of  $D(\infty\text{-Cat})$  and  $D(\infty\text{-Cat}/C)$ .

#### 28. The Whitehead theorem for $\infty\text{-groupoids}$

The "jar filling" lemma of the last section can be applied to our analogue of CW-complexes (simplicial sets formed by gluing simplices  $\Delta^n$  along their boundaries). Potentially we will use a well order somehow reducing to the case of homotopy-extension to a single jar.

 $\vec{\Omega},$  the analogue of loop space, is the internal hom functor [I,-] :  $\infty\text{-Grpd}\longrightarrow\infty\text{-Grpd}.$ 

 $\vec{\Omega}$  is to internal groupoids as  $\vec{\omega}$  is to internal G-presheaves.  $\vec{\omega}$  is also called homotopy pullback, but this by no means standard notation for homotopy pullback at all. These functors will later be used to produce functors  $\vec{P}: D(\infty\text{-Cat}) \longrightarrow \text{IntCat}\ D(\infty\text{-Cat})$  and  $\vec{p}: D(\infty\text{-Cat/C}) \longrightarrow \text{IntPrShf}\ D(\infty\text{-Cat/C})$  ( $\vec{P}$  C).

### Chapter 9: Internal Groupoids and their Actions

In this next section, we continue the approach to Whitehead theorem (b) by defining the category of internal groupoids and internal G-presheaves.

#### 32. IntGrpd : Cat $\longrightarrow$ Cat

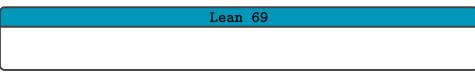

Internal groupoids can be defined in any category with pullbacks.

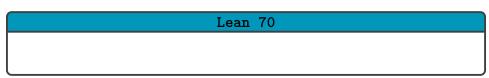

```
Lean 68

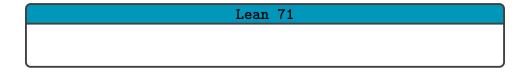

/-
structure internal_groupoid (Γ : category with

    pullbacks) where
    Obj := D(Γ).Obj

-- Dom :=
-- Cod
-- Idn
-- Fst
-- Snd
-- Cmp
-- Id<sub>1</sub>
-- Id<sub>2</sub>
-- Ass
-- Com
-/
```

Lean 72

Lean 73

Lean 74

Lean 75

 ${\tt def\ IntGrpd\ (\Gamma\ :\ pulback\_system)\ :\ Cat.Obj\ :=\ sorry}$ 

Lean 76

notation "Grpd\_("  $\Gamma$  ")" => IntGrpd  $\Gamma$ 

#### 33. IntAct

Here we define internal groupoid actions.

```
Lean 77
/-
structure groupoid_presheaf (\Gamma : category with
\rightarrow pullbacks) (G : internal_groupoid \Gamma) where
  Obj : D(Γ).Obj
-- Mor : D(\Gamma).
-- Dom : D(\Gamma).
-- Cod : D(\Gamma).
-- Fst : D(\Gamma).
-- Snd : D(\Gamma).
-- Idn : D(\Gamma).
-- Idn : D(\Gamma).
-- Cmp : D(\Gamma).
-- Id_1 : D(\Gamma).
-- Id_2 : D(\Gamma).
-- Ass : D(\Gamma).
-- Com : D(\Gamma).
```

#### Lean 79

Lean 80
Lean 81
Lean 82
Lean 83

#### 34. The Internal Groupoid Principal

The internal groupoid principal stems from the simple observation that the pull-back of a map by itself (minding matters of existence of pullback for a moment) forms the morphism component of an internal groupoid. It already been observed that it forms the morphism component of an internal category. Here, we also extend the observation that the derived homotopy pullback of an  $\infty$ -functor between  $\infty$ -groupoids by itself forms, in a derived category, an internal groupoid.

#### 35. The Internal Groupoid Action Principal

The internal groupoid action principal stems from the simple observation that the pullback of a map by another forms the morphism component of an internal groupoid action. It already been observed that it forms the morphism component of an internal C-presheaf. Here, we also extend the observation that the derived homotopy pullback of an  $\infty$ -functor between  $\infty$ -groupoids by another forms, in a derived category, an internal groupoid action.

This section will construct  $\vec{P}\!\!,$  which is an internal groupoid that one obtains from any  $\infty\text{-groupoid}.$ 

This section will construct the functor  $\vec{p}$  mentioned in the introduction. Later we will add a theorem stating that this functor is infact naturally isomorphic to a functor constructed using  $\vec{\omega}$  and constructiosn from Eilenberg-Moore theory.

### Chapter 10: The Puppe Sequence for $\infty ext{-Groupoids}$

In this chapter we construct the Puppe sequence for  $\vec{\pi}_n$ . Note: one joint in this exact sequence consists not of a map but an action.} This will be used in the next chapter two establish the second of the six categorical equivalences mentioned in the introduction.

## Chapter 11: The Groupoid Fixed Point Principals

After the last section is complete, we will be in a place to prove the internal groupoid and internal groupoid presheaf delooping principals, which are the third and fourth of the six categorical equivalences mentioned in the introduction.

```
Lean 84

-- def BInfGrpd: (Cat. Hom\ Grpd_(\infty-Grpd)

-- D(\infty-Grpd)).Obj:= sorry
```

#### Lean 85

```
 \begin{array}{lll} -- & def \ Par \ (C : D(\infty - \mathbb{Col}).0bj) : Shf_(\infty - \mathbb{Col}) \\ & \hookrightarrow & (P_{-}(\infty - \mathbb{Col}) \ C \ C \ (\mathbb{1}_{-}(D(\infty - \mathbb{Col})) \ C)) \ \longrightarrow \\ & \hookrightarrow & (Cmp_{-}(\infty - \mathbb{Col}) \ C) := sorry \end{array}
```

#### Lean 86

#### 40. The Internal Groupoid Fixed Point Principal

```
Lean 87

/-

def internal_groupoid_delooping_principal (Γ :

→ pulback_system) : Type := D(Γ) ≃_(Cat)

→ Grpd_(Γ)

-/
```

### Lean 88

```
-- def internal_groupoid_delooping_principal_proof :

→ internal_category_delooping_principal ∞-Cot :=

→ sorry
```

#### 41. The Internal Presheaf Fixed Point Principal

```
Lean 89

/-

-- def

-- internal_groupoid_presheaf_delooping_principal

-- (\Gamma : pullback_system) (C : D(\Gamma).Obj) : Type :=

-- Shf_{\Gamma}(\Gamma) (P (1_{\Gamma}(D(\Gamma)) C)) \cong Der_{\Gamma}(\Gamma) C

-/
```

PART 3: BASED CONNECTED  $\infty\text{-GROUPOIDS}$ 

### Chapter 12: $\infty$ -Grpd<sub>0</sub>

Here we define the mentioned categories  $D(\infty\text{-}Grpd_0)$  of connected based  $\infty$ -groupoids and  $D(\infty\text{-}Grpd_0/G_0)$  mentioned in the introduction.

### Chapter 13: The Whitehead Theorem

In this chapter we prove the following (which we have called Whitehead Theorem (c)):  $\forall (E:D(\infty\text{-}Grpd_0)), \forall (B:D(\infty\text{-}Grpd_0)), \forall (f:E \longrightarrow B), \forall (G:E \longrightarrow B), (\forall (n:Nat), (\pi_n F = \pi_n G)) \longrightarrow F = G$ , where  $\pi_n$  is notation for  $\pi$  n.

This can be shown using CW-replacement and induction on n. Fibrant replacement of an object X entails replacing an object in  $\infty$ -Grpd $_0$  with a CW-object (an object made by successively glueing in higher and higher simplices along their boundaries obtaining a sequence  $X_n$ ). Given an equality  $\pi_{n+1}(f) = \pi_{n+1}(g)$  and a homotopy equivalence  $h_n: \Delta^1 \times X_n \longrightarrow Y$  between  $f|_{X_n}, g|_{X_n}: X_n \longrightarrow Y$ , we construct an extension of the homotopy equivalence  $\Delta^1 \times X_{n+1} \longrightarrow Y$ .

### 45. HEP for based connected $\infty\text{-groupoids}$

This

#### 46. The Whitehead theorem

Here we show the Whitehead theorem proper.

Chapter 14: Internal Groups

#### 47. Grp\_(Γ)

```
Lean 90
/-
structure internal_group \dots where
 Obj := D(\Gamma).Obj
-- Dom :=
-- Cod
-- Idn
-- Fst
-- Snd
-- Cmp

-- Id<sub>2</sub>
-- Ass
-- Com
                          Lean 91
                          Lean 92
                          Lean 93
                          Lean 94
```

Lean 95

Lean 96

#### Lean 97

-- def IntGrp ( $\Gamma$  : pulback\_system) : Cat.Obj :=  $\rightarrow$  sorry

#### Lean 98

-- notation "Grp\_("  $\Gamma$  ")" => IntGrp  $\Gamma$ 

#### 48. $Act_(\Gamma)$ G

Here we define internal group actions. These will be important when we talk about G-principal bundles (themselves defined as internal group actions in the derived category of an overcategory).

```
Lean 99

/-
structure group_action (Γ : pullback_system) (G :

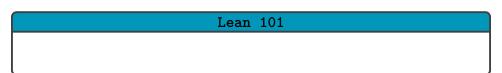

→ internal_groupoid Γ) where

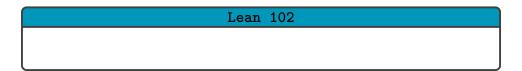

Obj : D(Γ).Obj

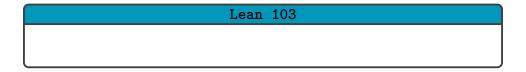

-- Mor : D(Γ).

-- ...

-/
```

Lean 104
Lean 105

#### 49. The Internal Group Principal

The internal group principal stems from the simple observation that the loop space forms a component of an internal group.

#### 50. The Internal Group Action Principal

The internal group actions principal stems from the simple observation that the homotopy fiber forms a component of an internal group action.

This section will construct P, which is an internal group that one obtains from any based connected  $\infty\text{-groupoid}.$ 

This section will construct the functor p mentioned in the introduction. Later we will add a theorem stating that this functor is in fact naturally isomorphic to a functor constructed using  $\omega$  and using constructions from Eilenberg-Moore theory.

## Chapter 15: The Puppe Sequence for Based Connected $\infty ext{-}\mathsf{Groupoids}$

This chapter establishes the well know Puppe sequence for the based homotopy groups  $\pi_n$ . This is the well known Puppe sequence of homotopy groups.

## Chapter 16: The Group Fixed Point Principals

B is the ordinary classifying space, and it is defined on internal groups in  $D(\infty\text{-}\!\operatorname{Grpd}_0).$ 

```
Lean 106

-- def BInfGrpd: (Cat. Hom Grpd_{-}(\infty-Grpd)

D(\infty-Grpd)). Obj:= sorry
```

B is the ordinary classifying space, and it is defined on internal group actions in  $D(\infty\text{-Grpd}_0)$ .

```
Lean 107

-- def Par (C : D(\infty - \mathbb{C}\text{ot}) . 0bj) : Shf_(\infty - \mathbb{C}\text{ot})

\hookrightarrow (P_{-}(\infty - \mathbb{C}\text{ot}) C C (1_{-}(D(\infty - \mathbb{C}\text{ot})) C)) \longrightarrow

\hookrightarrow (Cmp_{-}(\infty - \mathbb{C}\text{ot}) C) := sorry
```

```
Lean 108

-- notation "b" => Par
```

#### 55. The Internal Group Fixed Point Principal

For a based connected space X, the path space [I,X] is weak equivalent to the loop space  $\Omega X$ . This observation will allow us to prove that the category of based connected  $\infty$ -groupoids is internal groups in itself.
